Abstract

The introduction of biofuels is one of the objectives of the European Union. For this reason, measures to promote the production and consumption of this product have been implemented, such as tax exemptions, fixing a minimum amount of mixture or the introduction of public transport that consume biofuels. In this paper, we test different factors that can affect the introduction of biodiesel in the Spanish gasoline market. These factors are mainly the level of local competition, technical difficulties and local government action. Empirical evidence shows that a higher level of competition, more buses that consume biodiesel and a lower adjustment costs increase significantly the probability of sell biodiesel at service stations. These results show how the promotion of competition and public procurement of vehicles can improve the commercialization of biofuels.

1. Introduction

The introduction of biofuels to the automotive market is a clear objective within the European Community (EC). In fact, EC has established a policy that sets minimum levels of biofuels sold in each member state. The objective of the European Community to replace fossil fuels with biofuels is twofold: firstly, to reduce its reliance on foreign energy (since it has virtually no oil production) and, secondly, to reduce the emission of pollutants to help limit climate change. Therefore, the EU set 2% of all petrol and diesel at 31 December 2005 and 5.75% at 31 December 2010 as targets for biofuels.³

Member states can themselves introduce measures to encourage the consumption of biofuels to reach this objective. These measures have focused on tax exemption for firms that invest in technology to produce biofuels as well as the charging of a lower consumption tax for biofuels.

In Spain, a fiscal deduction of 10% for renewable energy investments in corporation tax and the removal of the special tax on fuel until 2013 have been introduced as a national policy measure.⁴ Besides, the Ministry of Industry, Tourism and Trade is considering the introduction of new measures to encourage the consumption of biofuels, introducing in the draft Law on Energy Efficiency and Renewable Energy the requirement to have a biofuel pump at all those service stations that sell more than 3 million gallons per year.

In this paper, we analyse the role of market structure, local government action and technical problems plays in the penetration of biofuels and how the public policy can encourage the introduction of biodiesel.

Although in recent years the effect of biofuel production on economic development has been deeply analysed (Ryan et al., 2006; Frondel and Peters, 2007; Charles et al., 2007; Hahn and Cecot, 2009), regarding the effect of fiscal policy on the development of industry

³ Directive 2003/30/EC of the European Parliament and the Council of 8 May 2003.

⁴ These measures are included in the Order of the Ministry of Industry, Tourism and Trade ITC/2877/2008.

(Wassell and Dittmer, 2006; Vedenov and Wetzstein, 2008) and the effect on countries producing raw materials (Pousa et al., 2007; Peters and Thielmann, 2008; Lamers et al., 2008; Gucciardi and de Souza, 2009; Leite et al., 2009; Bastian-Pinto et al., 2009; Mathews and Goldsztein, 2009)⁵, there is no, as far as we know, analysis of what promotes the penetration of biodiesel in retail sales, a key element to ensuring the survival of the industry⁶. In fact, the unique study that has examined empirically the introduction of biofuels is Corts (2010) which analyzes the penetration of Ethanol in the U.S. market. However, as well as the author explains, the case is significantly different from Ethanol and biodiesel because Ethanol cannot be consumed by conventional cars aspect that decisively affects the retailing of this type of biofuel.

This article presents a set of contributions on the literature, but mainly it should be noted that this is the first time that analyzes factors affecting the penetration of biodiesel in the market of traditional fuels. Equally novel set of explanatory factors for the decision to sell biodiesel or not are used in the empirical analysis. Within these explanatory factors include the level of local competition in the market, the differences in cost between the stations, the technical difficulty of selling this type of biofuel and the possible influence of local government in developing the biodiesel market in Spain.

The empirical results show how the level of competition, costs differences and technical difficulties of the service stations significantly affect the decision to sell or not biodiesel. Similarly, the results show how the characteristics and the measures introduced by local governments can significantly affect the market development of biodiesel.

After this introduction, the rest of the paper is structured as follows: the main characteristics of the biodiesel market in Spain are explained in section 2; section 3 includes

⁵ An example on the environmental effect of the adoption of such fuels is Sartzetakis, S., and Tsigaris, P. (2005).

⁶ Articles like those of Rask (1998) and Luchansky and Monks (2009) have analysed the behaviour of supply and demand for bioethanol in the U.S., while focusing on the analysis of its elasticity and not on the diffusion or penetration of the product in the fuel retail market.

the database used in the econometric specification, which is developed in section 4. The results are shown in section 5. The article ends by presenting the main conclusions and policy recommendations.

2. The biodiesel market in Spain

In the market for biofuels, biodiesel plays a predominant role in the Spanish market, since the production and consumption of bioethanol are much smaller than in the U.S. Most European countries, contrary to what happens in America, share this feature.⁷ For this reason, we focus on the biodiesel market.⁸

In this market, as pointed out by the report of the Spanish regulator Comisión Nacional de la Energía (CNE) (2005), there are numerous barriers that limit development, both with technical and related characteristics. With respect to the technical aspect, we find the crystallization and solidification of fuel microbial growth during pipeline transport, instability in storage and solvent power and the incompatibility with some plastic components in the diesel engines of some vehicles manufacturers.

Papers related to the characteristics of the biofuel market identify some problems: the high costs of raw materials and production; regulatory uncertainties, mainly in agriculture, which creates uncertainty about the availability of raw materials in the future; the absence of assurances from the producers of vehicles on the proper functioning of the engines; the lack of information for users; and, finally, the poor integration of biofuels into the distribution chain of conventional fuels.

As also indicated by CNE (2005), technical barriers should not be insurmountable for market development, as they can be solved relatively easily in the production,

⁷ EU Climate Package includes attempting to renewable sources. For example, 10% of transport fuels will have to come from renewables, including biofuels. The Commission wants to ensure that only biofuels achieving a real cut of at least 35% in CO₂ emissions will be allowed.

⁸ It is useful to note that biodiesel is essentially made from vegetable oils such as rape seed, conola, cotton and palm seed oils, which implies significant competition with health and food markets that also use vegetable oils.

transportation and marketing of biodiesel blended with conventional fuel in percentages of up to 30%, as is the case of Spain.

Concerning the second type of barrier, the high costs of raw materials and production as well as the poor integration of biofuels into the distribution chain of conventional fuels are, without doubt, the most important.⁹

Major steps taken by European countries to compensate for the high costs of raw materials and production, as we noted, have been tax exemption, partial or total. For the specific case of Spain, the main legislative reference is the Order of the Ministry of Industry, Tourism and Commerce ITC/2877/2008 promoting the use of biofuels and the like for transport and the Law 34/1998, which established annual targets for biofuel use in the Spanish territory. Among the tax measures introduced in this Order are the establishment of a zero tax rate on biofuels until 31 December 2012.¹⁰ This exemption seeks to compensate for the higher cost of biofuel production with respect to traditional fuels and it takes into account their lower polluting capacity.

Measures to promote research and development techniques that reduce production costs have been established in the production segment.¹¹ In addition to these tax measures, a regulation that set the minimum amounts of biofuels that operators must compulsorily consume has been passed. These biofuels are consumed by mixing with conventional fossil fuels.

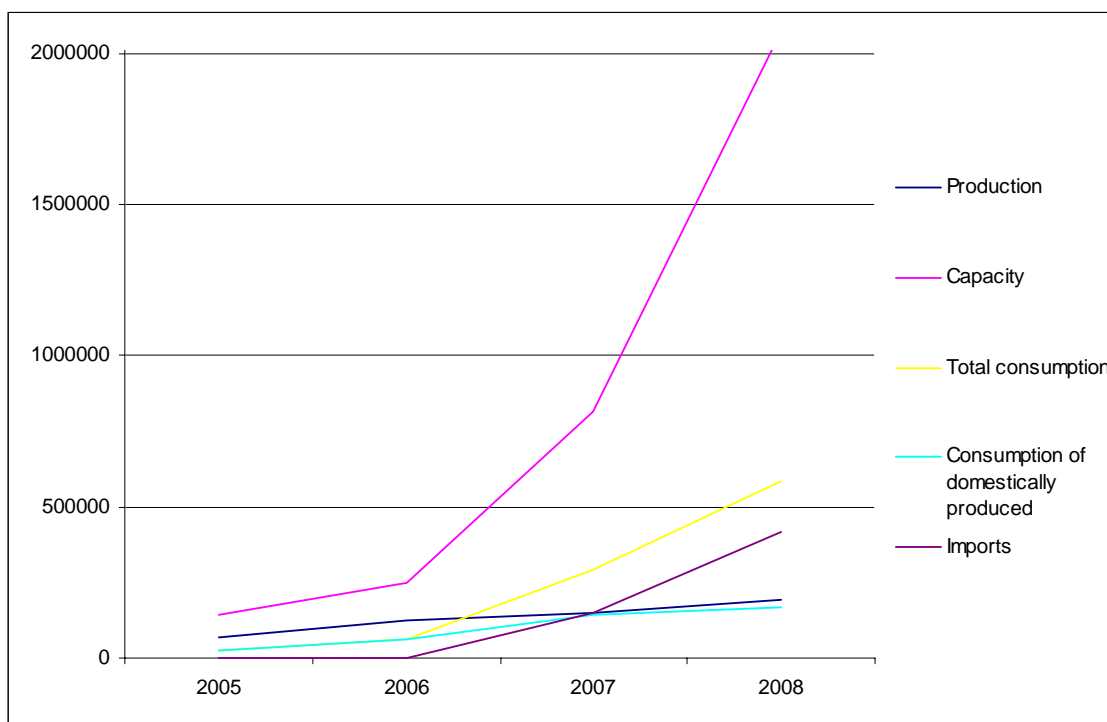

⁹ Although there is some uncertainty about the future availability of raw materials, the existence of an international market to some extent helps to overcome that barrier. Similarly, there are already many automobile manufacturers that ensure the smooth operation of their vehicles in the case of using biofuels. Concerning the lack of information, measures to identify suppliers of biofuel and diffusion measures of the environmental benefits of biofuels have been instituted.

¹⁰ Article 6.5 of Law 53/2002 of 30 December.

¹¹ The latter stresses Law 55/1999 of 29 December on fiscal administrative and social order, where amending Articles 33 and 35.4 of Law 43/1995 on corporate income tax look at the tax deductions for activities of research, development and technological innovation and investment in environmental protection. Other investment credits are include in: Law 24/2001 of 27 December on fiscal, administrative and social order amending Article 122 of Law 43/1995.

Due to these measures production capacity shows a remarkable increase in recent years.¹² However, they have not yielded a competitive Spanish market for biodiesel, so it has lost market share in recent years, resulting in capacity utilization rates of biodiesel production plants that are economically unsustainable.

Figure I. Capacity, production and biodiesel imports in Spain. Tonnes per year

Source: APPA Biocarburantes

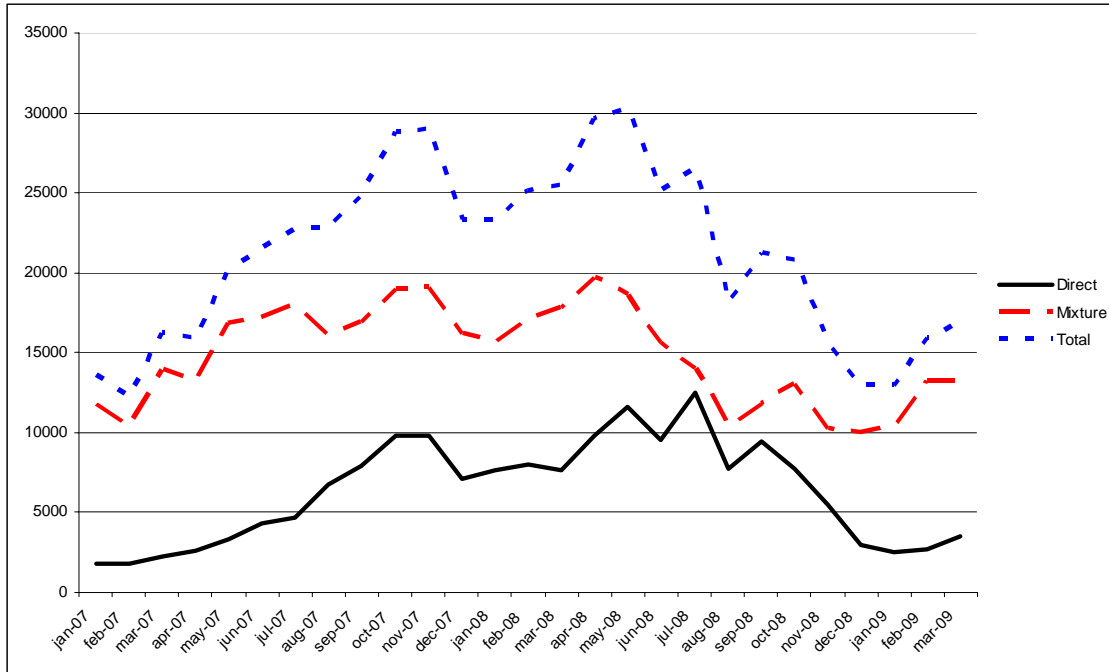

From Figure I and the table of Annex I, we can discern that only 4 of the 36 plants in 2008 (11%) are at a capacity utilization above 50%. Another 9 plants (25%) produced with a level of capacity between 10 and 50%, while the remaining 64% (23 plants) used between 0 and 10% of their available capacity.

One of the main reasons that consumption does not follow the path of production capacity is its limited inclusion in the distribution chain of conventional fuels. Thus, the percentage of service stations that dispense biodiesel is very small: only 8.6% of gas stations in our

¹² Annex I includes the list of biodiesel production plants operating in Spain during 2008 and those planned for launch during 2009.

sample. This can also be inferred from the trend in the consumption of biodiesel in the past 2 years.

Figure II. Monthly evolution of the consumption of biodiesel. Spain. 2007–2009

Source: Corporación de Reservas Estratégicas de Productos Petrolíferos (CORES)

As shown in Figure II, the total consumption of this biofuel has fallen since mid 2008 at a monthly negative average rate change of 4.7%, especially in regard to direct sales, although its use for increasing the octane of conventional diesel (the “mixture” curve in Figure II) has also suffered a substantial reduction.

Summarizing the biodiesel market outlook for Spain is not encouraging. The production segment is oversized, with a production capacity of 2,070,020 tons per year in 2008, 12 times the consumption that occurred in that year. Also, the segment is clearly not competitive with foreign producers, as evidenced by the increase in imports in recent years. These facts result in the economic infeasibility of a large number of existing plants, unless consumption increases further in the coming years, both in Spain and Europe.

In the retail marketing segment, the integration of biodiesel into channels of conventional fuels is almost zero, limiting the consumption of this fuel and decreasing the viability of the

productive segment. As we shall see later, an element that may be helping the lack of penetration of biodiesel in the retail segment is the reduced competition in the Spanish gasoline market, as stated by Perdiguero (2010) and Perdiguero and Jiménez (2009).

3. Data

In order to estimate how the level of competition may affect the adoption of a new product such as biodiesel, we have information on all the service stations operating in the four major Spanish cities: Madrid, Barcelona, Seville and Bilbao.¹³

For each of the station we have information on whether or not biodiesel is sold, and the area of each gas station in meters squared. Information on whether or not the gas station sells biodiesel was obtained from the website of the Ministry of Industry, Tourism and Trade. The surface of each of the stations has been estimated through information obtained from Google Earth. Using this computer program calculates the dimensions of each of the stations to calculate the surface later.

For each of the stations we have obtained also the number of competitors who have a half mile. This calculation required the georeferencing of each of the 243 petrol stations, fixing the longitude and latitude and calculating the Euclidean distance to other stations of different brands, as a proxy for competition in the market.¹⁴ This calculation was performed using the Matlab software.¹⁵ Once we had calculated this distance, we obtained the number of service stations within half a mile.¹⁶

Following this approximation we have also calculated the biodiesel production capacity that exists 30 miles away from each station. To obtain this information we have georeferenced position of each of the biodiesel production plants in Spain and later to calculate which one

¹³ We have information on the ten biggest cities in Spain in terms of population but only in the four mentioned is there any point of sale that provides biodiesel.

¹⁴ In the Spanish gasoline market, there is no competition between the stations of the same brand as the company's wholesale division fixes the final retail price directly or indirectly. Thus, only the number of stations that are of different brands was calculated.

¹⁵ The Matlab code for the calculation of these distances is available on request from the authors'.

¹⁶ 1/2 mile = 804.672 metres.

is at a distance of less than 30 miles and finally we add the production capacity of these plants. The address of each producing plants are obtained from the company APPA biofuels.

As demand variables we obtained the population and population density of each of the four cities. This information was obtained from the National Statistics Institute (INE). We have also created a dummy variable that takes value 1 if the station is in one of the main entry/exit roads of the city and 0 otherwise.

Regarding the variables related to local government we have constructed a dummy variable that takes value 1 if the government is from the right and 0 if the government is from the left. This information was obtained from the website of the Ministry of Interior. We also have information on the percentage of public transport buses that consume biodiesel respect the total bus fleet. Finally we have constructed a dummy variable that takes value 1 if the provision of urban transport by bus is performed by a private company and zero if it is provided publicly. This information has been obtained from the websites of the various urban transport companies by bus.

The next table shows the descriptive statistics of the variables mentioned above.

Table I. Descriptive statistics

	Obs.	Mean	Std Dev.	Min.	Max.
<i>No. Comp_i</i>	245	0.849	1.078	0	5
<i>No. Comp_i²</i>	245	1.878	3.592	0	25

Source: Authors' calculations.

Of the total of 245 service stations in the 4 cities considered, an average of 1 competitor in half a mile (0.849) is not achieved. The minimum number of competitors in that distance is 0 and the maximum is 5. Regarding the distribution by city, Madrid has more than half the stations, followed by Barcelona, Seville and Bilbao.

4. Hypothesis and empirical approximation

Para aproximar que elementos influyen en la decisión de comercializar o no biodiesel por parte de las gasolineras estimamos empíricamente la siguiente expresión:

$$Y_i = \beta_0 + \beta_1 No.Com_i + \beta_2 No.Comp_i^2 + \beta_3 Cap.30miles_i + \beta_4 Pop_j + \beta_5 Pop.Dens_j + \beta_6 MainWay_i + \beta_7 Sur_i + \beta_8 Right_j + \beta_9 Bio.Bus_j + \beta_{10} Priv_j + \varepsilon_i$$

where Y_i is a dummy variable that takes the value 1 if the service station "i" sells biodiesel and 0 otherwise. This decision depends on the number of rivals who have a service station within half a mile ($No.Comp_i$) and its square ($No.Comp_i^2$), production capacity of biodiesel

in 30 miles, population and density of population, whether the gas station is located on a main road of the city, the area occupied by the gas station and a set of variables of the local government, including whether local government is from the right or from the left, whether to privatize the bus transport, and the percentage of biodiesel buses on the total fleet. Next we discuss the different hypotheses we have for different groups of variables.

Level of local competition

One of the first aspects that can affect the decision to sell or not biodiesel is the level of competition in the market. In the Industrial Organization literature there is huge empirical evidence on the relationship between market structure and the introduction of a new product, if we understand the latter as an innovation.¹⁷ The first empirical evidence followed the idea proposed by Schumpeter (1939), which specified a negative relationship between the level of competition and innovation processes. Other authors have found, however, positive relationships between competition and innovation, such as Nickell (1996) and Blundell, Griffith and van Reenen (1999).

In both cases, the authors use linear approximations, although Scherer (1967) had already demonstrated that the relationship between these two variables is not linear but presents an inverted U shape: it grows in the presence of relatively few competitors to reach a peak from which, by introducing more firms, the level of innovation is reduced. This empirical evidence has been contrasted by Aghion et al. (2005) for a large panel of firms in the UK. Surprisingly, there are not a large number of empirical articles analysing the existence of this nonlinear relationship between competition and innovation and even fewer in an energy industry. For the construction of the variable that approximate the level of competition in the market, we followed the strategy for the sector described by Shepard

¹⁷ Schumpeter (1934) defines innovation as: “The introduction of a new good – that is one with which consumers are not yet familiar – or of a new quality of a good”. Therefore, the introduction of biodiesel in each of the pumps could be understood as a process of innovation.

(1993) and Perdiguero and Borrell (2010), estimating the number of competitors that exist within a distance of half a mile¹⁸.

To satisfy the inverted U relationship described in the literature, we should observe a positive sign in the coefficient of the number of rivals in half a mile ($\beta_1 > 0$) and a negative coefficient for its square ($\beta_2 < 0$). These are the two hypotheses that we test empirically.

Biodiesel production capacity

As indicated Corts (2010) biofuels cannot be transported with the rest of fuel through pipeline networks. This makes must be transported by tanker from the production site to the service station, which can be significantly more expensive for those outlets further away from the production centers. To capture this potential effect as an explanatory variable included refining capacity installed in an existing 30-mile radius from each station. The lower the installed production capacity around the gas station the higher the cost of obtaining supplies of biodiesel, since it will have to be acquired from more distant production sites. This makes that more production capacity installed around of gas stations more probability of selling biodiesel ($\beta_3 > 0$).

Demand factors

We also included variables that can affect fuel consumption in general, such as people living in the city and its density as well as a variable that reflects whether the gas station is located in one of the main routes of entry or exit of the city, element which may affect the demand for fuel. Gas stations that support higher demand may gain greater benefit and have more easily invest the necessary resources to sell biodiesel. However, a pump with higher demand of fuel nor necessarily have more demand of biodiesel. On the contrary, if

¹⁸ For a similar approximation see Chakravorty et al. (2008) which analyse the effects of US Clean Air Act on wholesale gasoline prices. To do that, they introduce the regulatory distance measure as a proxy for measuring market power to influence on prices. These authors conclude that higher distance, higher probability to increase prices.

demand is intensive fuel consumption can be very sensitive to the price over the number of kilometers traveled per liter of fuel. There is evidence in the literature (Corts 2010) that shows how biofuels have lower energy capacity than fossil fuels. Therefore, the sign of the demand variables will be determined in the econometric estimation.

Technical problems

Another element that can have a significant impact on the decision to sell or not biodiesel is the ease that has the service station to adapt a space for the sale of this type of biofuel. Biodiesel requires special storage tank, as an outlet made of materials capable of withstanding the most corrosive power of this type of fuel. So we expect that the larger petrol stations have more facilities to adapt the petrol stations to sell biodiesel. In our empirical approach we included the square meters of the service station as a proxy for the technical facility to bring the gas station to sell biodiesel, so we expect $\beta_7 > 0$.

Local Government characteristics

Finally we included a set of variables that describe the characteristics of local governments as well as his measures in the field of urban transport. A first element that we have considered is whether the government is from the right or from the left. Traditionally it is considered that governments from the left are more concerned about environmental problems and therefore be more prone to develop a market for biodiesel. We therefore expect that $\beta_8 < 0$.

One area in which local government can help to develop a market for biodiesel is the management of urban transport. In their study Corts (2010) show how the purchase of vehicles that consume Ethanol by the government encouraged the number of gas stations that sell these products. In our case, one way to help develop the market for biodiesel may be the purchase of buses which use this type of biofuel. We have therefore introduced a

variable that measures the percentage of total bus fleet that use biodiesel. We expect that this variable generate a positive effect on the probability of sell biodiesel ($\beta_9 > 0$). An element closely related to urban transport is whether the management is public or private. If we think in a private company that holds the concession for the service for a number of years, will probably have less incentive to make costly investments in new buses which use biodiesel, more so considering that the useful life of these buses can exceed the concession period. Therefore, urban transport services that are privatized can have a negative impact on consumption of biodiesel and therefore on the probability that a service station selling this type of fuel ($\beta_{10} < 0$).

Before proceeding to show the empirical results could indicate a number of aspects that we have to take into account. First, in addition to the institutional differences that may exist between regions and that would be reflected in the dummy variables for the cities, there may be heterogeneity among the service stations in the regions. To solve this problem of heteroskedasticity and to obtain a robust variance–covariance matrix, we introduce a cluster in a city that takes into account this feature of the data.

Secondly, there may be spatial autocorrelation in the residuals of our estimates. To check whether or not the errors are spatially correlated, we calculated Moran's test using the Stata command "spatcorr" as performed Corts (2010). As in the case of Corts (2010) Moran's statistic does not reject in any case the null hypothesis that errors are not spatially correlated.

Finally, we note that the sample is a small number of positive cases. In fact, 8.6% of the total number of service stations in these 4 cities offer biodiesel (21 outlets). This low level of values can lead to the logit estimator reaching results that might not be efficient. To solve this problem, we estimate the model described by a "complementary log-log model". This type of logistic model takes into account that the database can be unbalanced, because

there is either a low probability of occurrence or a high probability. The results obtained are shown in the following section.

5. Results

Table II contains the estimation using the "complementary log-log model",¹⁹ in seven different specifications depending on the number of variables included. These different specifications will help us verify the robustness of our analysis and show that there are problems of omission of relevant variables that might bias our results.

The estimates show that the coefficient of the number of rivals who are half a mile away is positive and significant in all cases as well as its square being negative and significant. This empirical evidence indicates that there seems to be an inverted U-shaped relationship

¹⁹ We do the same estimations using a logit estimator. Results do not change significantly.

between competition and opportunities to innovate in the market, as indicated by Aghion et al. (2005).

To show more clearly the inverted U relationship between the incorporation of biodiesel and the number of competitors in half a mile, we perform a series of simulations to determine the likelihood of its existence, as summarized in the figure below.

Figure III. Evolution of the probability of selling biodiesel depending on the number of competitors in half a mile

Source: Authors' calculations

As seen in Figure III, in all the specifications, the maximum probability is reached in a market structure with 2 opponents in less than half mile. Considering that the average rivals in our sample do not reach 0.9, we conclude that there is indeed potential for increasing the marketing of biodiesel incident to market structure, i.e. increasing the level of competition that exists today. We should note that Spain has one of the lowest densities of petrol per thousand inhabitants in all of Europe, which we estimate would explain, at least in part, the low level of commercialization of biodiesel.

The installed production capacity in 30 miles is positive and significant in all cases as we expected. Gas stations that have more production capacity of biodiesel installed near reduce their transport costs and increase the probability of introduce this type of biofuel.

Regarding the surface of the station is also positive and significant at 1% in all cases. This result confirms our hypothesis that larger stations have fewer technical problems to bring a tank and a pump to sell biofuels.

Regarding the demand variables, the population is negative and significant, while the population density is positive and significant. Finally, the variable measuring whether the service station was located in one of the main entry/exit roads of the city not statistically significant.

Finally, the variables that describe the characteristics of different local governments are all significant at one percent. The Right variable indicates that right-wing governments are probably less sensitive to environmental problems and this aspect have a significant negative effect on the probability of selling biodiesel. In this sense the variable Privatization shows how the privatization of urban transport management has a significant and negative effect on the probability of selling biodiesel. Finally we can observe how the percentage of buses that consume biodiesel shows a significant positive relationship with the probability of selling biodiesel. As in the case of Ethanol in the United States showed by Corts (2010), it seems that the creation of demand through increased fleet of buses that consume biodiesel helps increase the likelihood that service stations offer this biofuel.

6. Concluding remarks

The introduction of renewable energy to help reduce CO₂ emissions and therefore to comply with environmental commitments is a primary objective in Europe. Both in Europe and in Spain several incentives have been introduced for the development of the biofuel industry and more specifically biodiesel. As a result of these measures, there has

been a steady increase in production capacity in Spain, which contrasts with the moderate growth in demand and the strong increase in the percentage of imports. This fact causes many plants to operate below 10% of their capacity, a threshold that makes the continuing development of the market unviable.

To explain the low penetration of biodiesel consumption in Spain, we have discussed how service stations make the decision to offer this new product. Between the factors that may affect this decision we take into account the level of local competition, cost elements such as proximity to the production plants or the facility to adapt the service stations, demand elements, and finally characteristics of local governments.

The empirical results show that the relationship between the level of competition and the possibility of introducing the new product is nonlinear, inverted U specifically. The presence of one or two competitors within half a mile increases the probability of introducing the new fuel while having greater competitive pressure reduces the chance of having it. This relationship between innovation (considering introducing a new product as an innovation) and market structure is widely established in the literature of Industrial Organization.

Considering that Spain has one of the lowest densities of petrol stations in Europe, and that the transition from public monopoly to the free market cannot yet generate effective competition in the market, Spain can provide consumption levels of biofuels that are too low, at least in part, in relation to its market structure.

Another element that may play an important role in the development of biodiesel in Spain is the urban transport fleet. The existence of public enterprises to manage urban transport and increase the number of buses that consume biodiesel has a significant impact on market development of biodiesel.

Given the empirical results obtained in this study, a way to promote the consumption of such fuel would be to introduce more competition into the market, either through new entrants or by facilitating a change of brand of the retailers established in the market, which would mean that there are traders of different brands in each market. Also an active policy by local governments in the acquisition of buses which use biodiesel can help increase the number of gas stations that sell biodiesel.

Annex I. Production and projections of biodiesel production in Spain

Table A.I.1. Biodiesel plants in Spain on 31 December 2008

Firm	Locality	Province	Capacity (t)
Infinita Renovables	Castellón	Castellón	300000
Bioenergética Extremeña 2020	Valdetorres	Badajoz	250000
Bio-Oils Huelva I	Palos de la Frontera	Huelva	250000
Combustibles Ecológicos Biotel	Barajas de Melo	Cuenca	150000
Biocarburantes CLM	Ocaña	Toledo	105000
Biodiesel Aragón	Altorricón	Huesca	100000
Linares Biodiesel Technology	Linares	Jaén	100000
Biocom Energía	Algemesí	Valencia	75000
Biodiesel Caparroso	Caparroso	Navarra	70000
Biocombustible de Cuenca	Cuenca	Cuenca	50000
Ecoproductos Cast. La Mancha	Montalbo	Cuenca	50000
Bionet Europa	Reus	Tarragona	50000
Entabán Biocomb. Guadalquiv.	Sevilla	Sevilla	50000
Biodiesel Castilla la Mancha	Santa Olalla	Toledo	45000
Biodiesel de Andalucía 2004	Fuentes de Andalucía	Sevilla	40700
Combunet	Monzón	Huesca	40000
Energía Gallega Alternativa	Cerceda	A Coruña	40000
Bionor Berantevilla	Berantevilla	Álava	35320
Biocarburantes de Galicia	Begonte	Lugo	35000
Grupo Ecológico Natural	Llucmajor	Baleares	33000
Stocks del Vallés	Montmeló	Barcelona	31000
Hispanergy Puertollano	Puertollano	Ciudad Real	25000
Entabán Biocomb. Del Pirineo	Alcalá de Gurrea	Huesca	25000
Biocarburante Almadén	Almadén	Ciudad Real	21000
Biocarburante de Castilla	Valdescorriel	Zamora	20000
Diesol	Alcalá de Henares	Madrid	15000
Bioteruel	Albalate del Arzobispo	Teruel	10000
Comb. Ecol. Mediterráneo	Elda	Alicante	10000
Albabío Andalucía	Níjar	Almería	6000
Biocarbureros de Almanzora	Cuevas de Almanzora	Almería	6000
Biodiesel Carburantes	Carranque	Toledo	6000
Bercam	Los Yébenes	Toledo	6000
Bionorte	San Martín del Rei	Asturias	5000
Biocomb. De Castilla y León	San Cristóbal de Entrevías	Zamora	6000
Transportes Ceferino Martínez	Vilafant	Girona	5000
Asthor Biodiesel	Gijón	Asturias	4000
TOTAL			2070020
